Starting point: COST Action Infogest 2011-2015

Infogest aims at building an open international network of institutes undertaking multidisciplinary basic research on food digestion gathering scientists from different origins (food scientists, gut physiologists, nutritionists…).

Infogest targets three main scientific goals:

- Identify the beneficial food components released in the gut during digestion
- Support the effect of beneficial food components on human health
- Promote harmonization of currently used digestion models

The Human digestion – in a test tube

Harmonized IVD protocol

ABSTRACT

Recently, a static *in vitro* digestion (IVD) protocol was published by Minekus and coworkers (Minekus et al., 2014) within the COST INFOGEST network. The protocol, concentrating on physiological enzyme activities had the main goal to improve the comparability of experimental data between labs. The protocol was validated in several inter-laboratory studies using skim milk powder (SMP) and indeed demonstrated improved harmonization compared with previous experiments with individual IVD protocols (Egger et al., 2016). Although the enzyme activities and salt concentrations of the harmonized protocol are based on available human *in vivo* data, confirmation of the protocol's physiological relevance has been lacking until now. The main goal of the study was therefore to compare the harmonized IVD protocol with data from *in vivo* digestion. Towards this aim, an *in vivo* pig experiment with the same SMP as used for the validation of the IVD protocol was performed followed by a comparison of protein hydrolysis between *in vivo* and *in vitro* results. Protein hydrolysis at different levels was analyzed with gel electrophoresis, mass spectrometry, high performance liquid chromatography, and spectrophotometric o-phthaldialdehyde determination of free amino acids. Principle component analysis was used for graphical data comparison.

Milk proteins detected after gastric IVD corresponded to gastric and duodenal *in vivo* samples and intestinal IVD samples corresponded to distal jejunal *in vivo* samples. Peptides identified after the gastric phase of IVD, correlated with *in vivo* gastric samples ($r = 0.8$) and intestinal IVD peptides correlated best with in vivo samples collected from the median jejunum ($r = 0.57$). Free amino acids were in both systems mainly released during the intestinal phase of digestion. Protein hydrolysis in the harmonized IVD was similar to *in vivo* protein hydrolysis in pigs at the gastric and intestinal endpoints. Therefore, the harmonized static *in vitro* protocol is suited to study protein hydrolysis at these endpoints.

Milk protein digestion

ABSTRACT

Human jejunal digests after oral ingestion of casein and whey protein were collected by a nasogastric tube and protein degradation and peptide release was compared with that found in the digests of the same substrates using a standardised protocol. No intact casein was detected in the jejunal nor in the *in vitro* samples taken during the intestinal phase, while β-lactoglobulin was found in one hour-jejunal samples in agreement with the *in vitro* digestion. *In vivo* and *in vitro* digests showed comparable peptide profiles and high number of common sequences. A selective precipitation step was used to strengthen the identification of phosphorylated peptides. Most of the sequences found in jejunum, some of them not previously described, were also identified in the simulated digests. Common resistant regions to digestion were identified, revealing that the *in vitro* protocol constitutes a good approximation to the physiological gastrointestinal digestion of milk proteins.

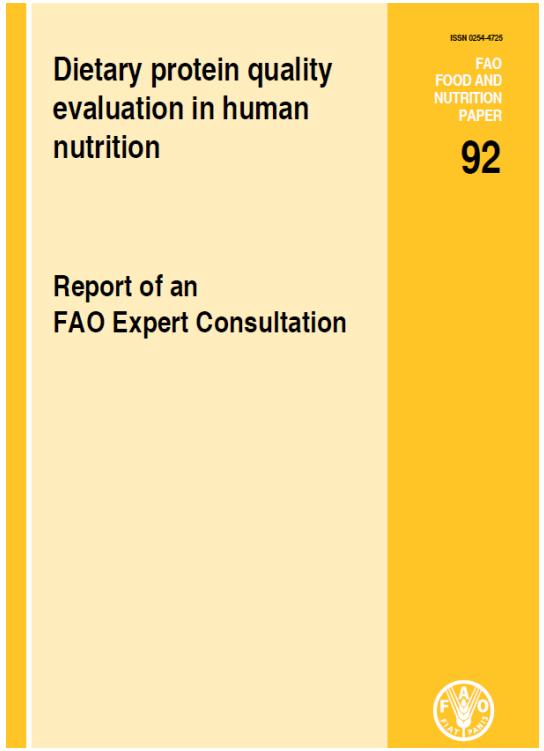
Dietary protein quality evaluation by FAO



Ileal digestibility

1. Further determine true ileal digestibility of protein and amino acids in a wider range of foods and determine the ileal digestible tryptophan content of human milk.
2. Develop non-invasive accurate methods to determine or predict true ileal dietary protein and amino acid digestibility in humans based on identified biomarkers.
3. Validate the use of animal model data (including providing more robust inter-species prediction equations for true ileal amino acid digestibility) to quantify ileal digestibility in humans, including relating digestibility to functional outcomes.
4. Determine more fully the role of the small intestinal and colonic microflora on ileal amino acid digestibility values.
5. Develop new bioavailability assays such as the reactive lysine assay, for other amino acids.
6. Develop and validate *in vitro* methods for predicting amino acid digestibility and bioavailability in humans.

DIAAS % = 100 x *lowest value* [*"Digestible IAA reference ratio"* for a given amino acid scoring pattern].

Note that the main difference between DIAAS and PDCAAS is that true ileal amino acid digestibility for the dietary indispensable amino acids is used rather than a single faecal crude protein digestibility value.
