Remote grazing management using Virtual Fencing (VF):

- Less workload → use of land potential
- High flexibility → adapted feeding
- Lower risk of injury → wildlife protection

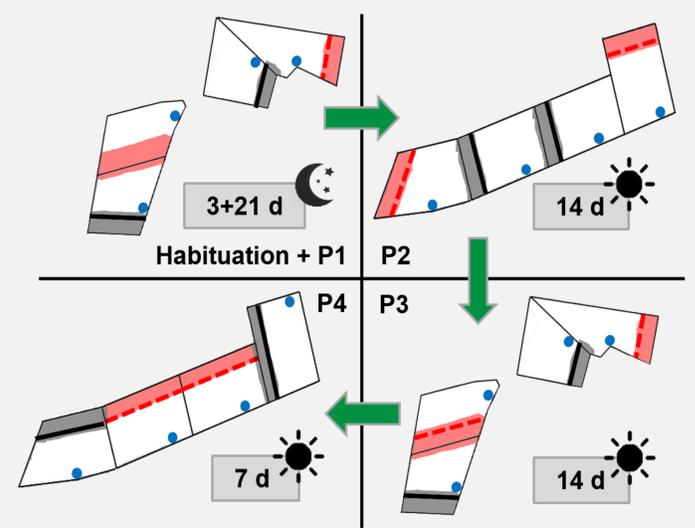

Grazing experiment

Animals

- 20 lactating cows, Holstein Friesian
- 4 groups (à 5 cows): K1/2 and T1/2
- Used to daily grazing, naive to VF

Methods

- Rotational grazing management
- 4 periods (P1-4)
- 4 paddocks (2x control, 2x VF treatment)

- Electric fence (Control)
- - - Virtual fence (Treatment)
- T C Exclusion zones
- ☾ ☀ night-/ daytime grazing
- Water

Measurements

- Stimuli (by VF collar) → each per cow of group T1/2
- Cortisol concentration (by milk sampling) → each day of Habituation → start, middle, end of P1-4

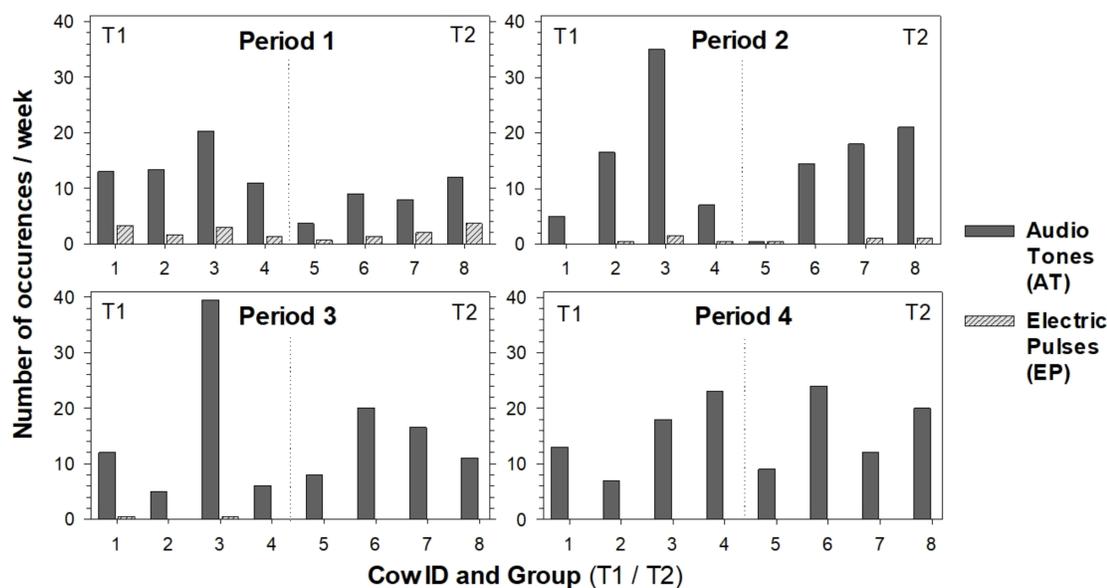

Conclusions

- All cows learned Virtual Fencing in rotational grazing management.
- Milk cortisol levels did not indicate increased stress to the cows.
- Individual learning must be considered for appropriate use of Virtual Fencing.

Research Questions

- Q1: Are cows able to learn VF in rotational grazing management?
 Q2: Does VF affect animal welfare related to milk cortisol levels?

Number of VF stimuli per cow & period

Milk cortisol levels per group & period related to time of sampling
